SDB CoRe Drosophila Oogenesis

Drosophila Oogenesis | Drosophila oogenesis occurs in an assembly line fashion within a structure called an ovariole. In the germarium, stem cells divide to produce another stem cell and cystoblast. The cystoblast divides 4 times to produce a cluster of 16 cells that remain connected to each other by cytoplasmic bridges called ring canals. One Drosophila oogenesis: Current Biology - cell.com

Another useful facet of Drosophila oogenesis is practical. The ovary is the single largest organ in the female fly and the oocyte the single largest cell; however, the ovary is not essential for survival, allowing for extensive manipulation. Drosophila Oogenesis - eLS: Essential for Life Science In the fruitfly Drosophila, oogenesis begins with the formation of a 16 cell cyst of interconnected germ cells, one of which will become an oocyte and mature into an egg. Cysts are produced by germline stem cells that remain active throughout the lifetime of the fly. The entire process of oogenesis, from germline stem cell to mature egg, takes about a week and depends on complex interactions

Symmetry Breaking During *Drosophila* Oogenesis

In *Drosophila*, the symmetry-breaking events that establish both the anterior-posterior (AP) and dorsal-ventral (DV) axes are completed at midstage of oogenesis, long before fertilization and egg deposition (Roth 2003). Ovarian development in *Drosophila* is tractable to extensive genetic screening
